## Section 1: Project Overview

The project we are working on is to build a classifier application which will find out the predictive accuracy of a selected data set using k-NN, Decision tree and Naive bayes algorithm. After finding out the predictive accuracy we have to select which algorithm have found the more correct predictive accuracy among the three algorithms. For this project we have used weka tools to run the algorithm on our data set.

## Section 2: Dataset Overview

Cancer cases registered and deaths for NZ population.

Source - Ministry of Health NZ

The file has cases registered by cancer codes (brain, breast, etc.) and the death (data slicers - Year, Gender, Cancer category)

This database contains 6 attributes.

Attribute Information

- 1) Year
- 2) Type (registered patients, death)
- 3) sex (All Sex, Male, Female)
- 4) numbers (total count of patients)
- 5) ICD codes (international cancer codes)
- 6) Cancer category (breast, prostate, neck etc.)

Data Source : Kaggle.com

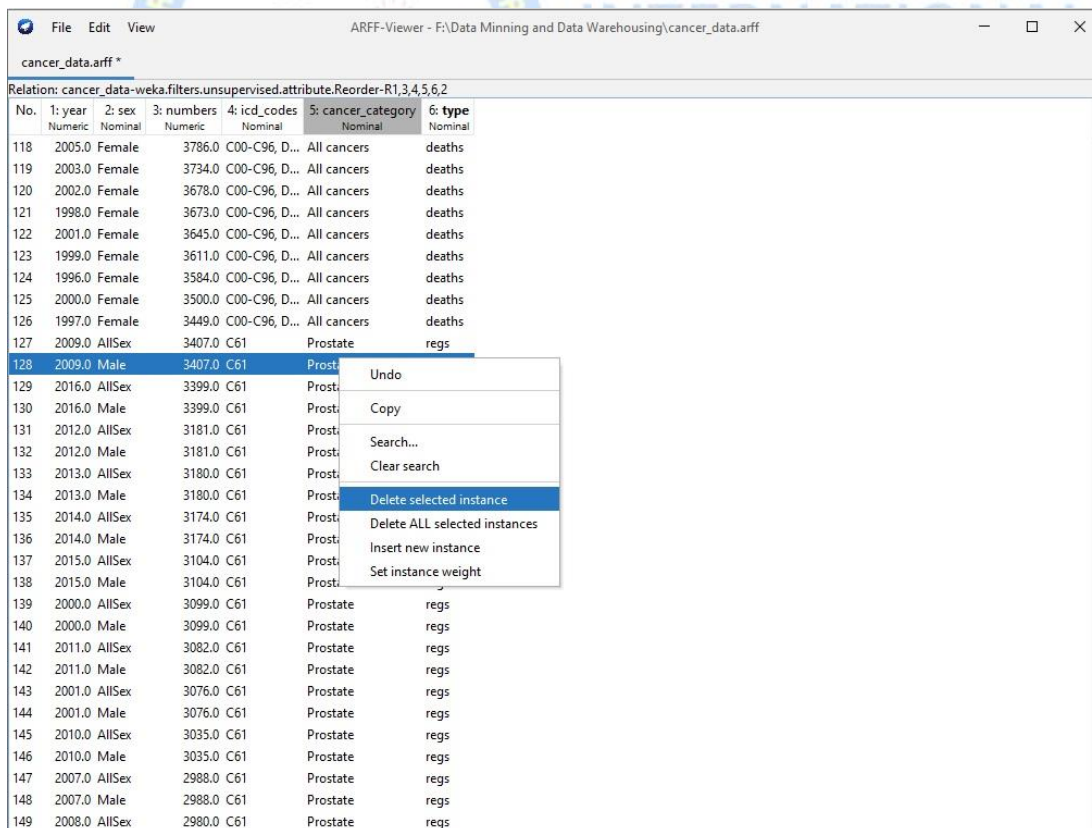

Url : <https://www.kaggle.com/cancer-data-set-registered-vs-death-by-yearsex>

## Section 3: Model Development

### 3.1 : Data preprocessing

Two strategies for dealing with missing attribute values were described:

- Discard Instances :
  - This is the simplest strategy: delete all instances where there is at least one missing value and use the remainder.
  - This strategy has the advantage of avoiding introducing any data errors.
  - Its main disadvantage is that discarding data may damage the reliability of the resulting classifier.
  - Together these weaknesses are quite substantial. Although the 'discard instances' strategy may be worth trying when the proportion of missing values is small, it is not recommended in general.

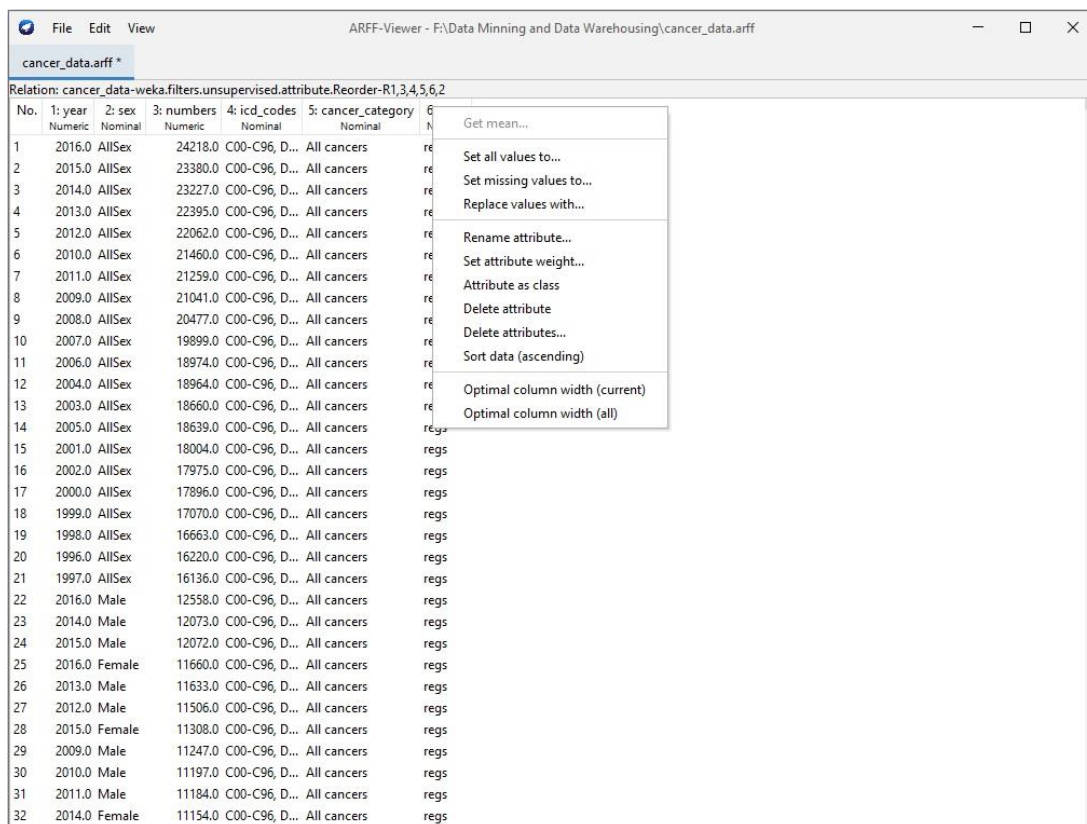

The screenshot shows the ARFF-Viewer application window. The title bar reads 'ARFF-Viewer - F:\Data Mining and Data Warehousing\cancer\_data.arff'. The menu bar includes 'File', 'Edit', and 'View'. The main window displays a table with the following columns: 'No.', '1: year', '2: sex', '3: numbers', '4: icd\_codes', '5: cancer\_category', and '6: type'. The table contains 20 rows of data. Row 128 is selected, and a context menu is open over it, showing options: 'Undo', 'Copy', 'Search...', 'Clear search', 'Delete selected instance' (highlighted), 'Delete ALL selected instances', 'Insert new instance', and 'Set instance weight'.

No.	1: year	2: sex	3: numbers	4: icd_codes	5: cancer_category	6: type
	Numeric	Nominal	Numeric	Nominal	Nominal	Nominal
118	2005.0	Female	3786.0	C00-C96, D...	All cancers	deaths

Figure 1: Discard Instance

- Replace by most frequent/average value :
  - With this strategy any missing values of a categorical attribute are replaced by its most commonly occurring value in the training set.
  - Any missing values of a continuous attribute are replaced by its average value in the training set.

The screenshot shows the ARFF-Viewer application window. The title bar reads "ARFF-Viewer - F:\Data Mining and Data Warehousing\cancer\_data.arff". The menu bar includes "File", "Edit", and "View". The main window displays a table with the following columns: "No.", "1: year", "2: sex", "3: numbers", "4: icd\_codes", "5: cancer\_category", and "6: ". The table contains 32 rows of data. A context menu is open over the "cancer\_category" column, showing options such as "Get mean...", "Set all values to...", "Set missing values to...", "Replace values with...", "Rename attribute...", "Set attribute weight...", "Attribute as class", "Delete attribute", "Delete attributes...", "Sort data (ascending)", "Optimal column width (current)", and "Optimal column width (all)".

### 3.2 : Naïve Bayes

Naive Bayes is a simple technique for constructing classifiers: models that assign class labels to problem instances, represented as vectors of feature values, where the class labels are drawn from some finite set. There is not a single algorithm for training such classifiers, but a family of algorithms based on a common principle: all naive Bayes classifiers assume that the value of a particular feature is independent of the value of any other feature, given the class variable. An advantage of naive Bayes is that it only requires a small number of training data to estimate the parameters necessary for classification

The screenshot shows the Weka Explorer application with the 'Classify' tab selected. The 'Classifier' dropdown is set to 'NaiveBayes'. Under 'Test options', 'Cross-validation' is selected with 'Folds' set to 5. The '(Nom) type' dropdown is also visible. The 'Start' button has been clicked, and the 'Classifier output' pane displays the results of a 5-fold cross-validation.

Figure 3: Naive Bayes Model developed using weka Tool

### 3.3 : K-NN

The k-nearest neighbours' algorithm (k-NN) is a non-parametric supervised learning method. It is used for classification and regression. In both cases, the input consists of the k closest training examples in a data set. The output depends on whether k-NN is used for classification or regression:

In k-NN classification, the output is a class membership. An object is classified by a plurality vote of its neighbours, with the object being assigned to the class most common among its k nearest neighbours (k is a positive integer, typically small). If  $k = 1$ , then the object is simply assigned to the class of that single nearest neighbour.

In k-NN regression, the output is the property value for the object. This value is the average of the values of k nearest neighbours.

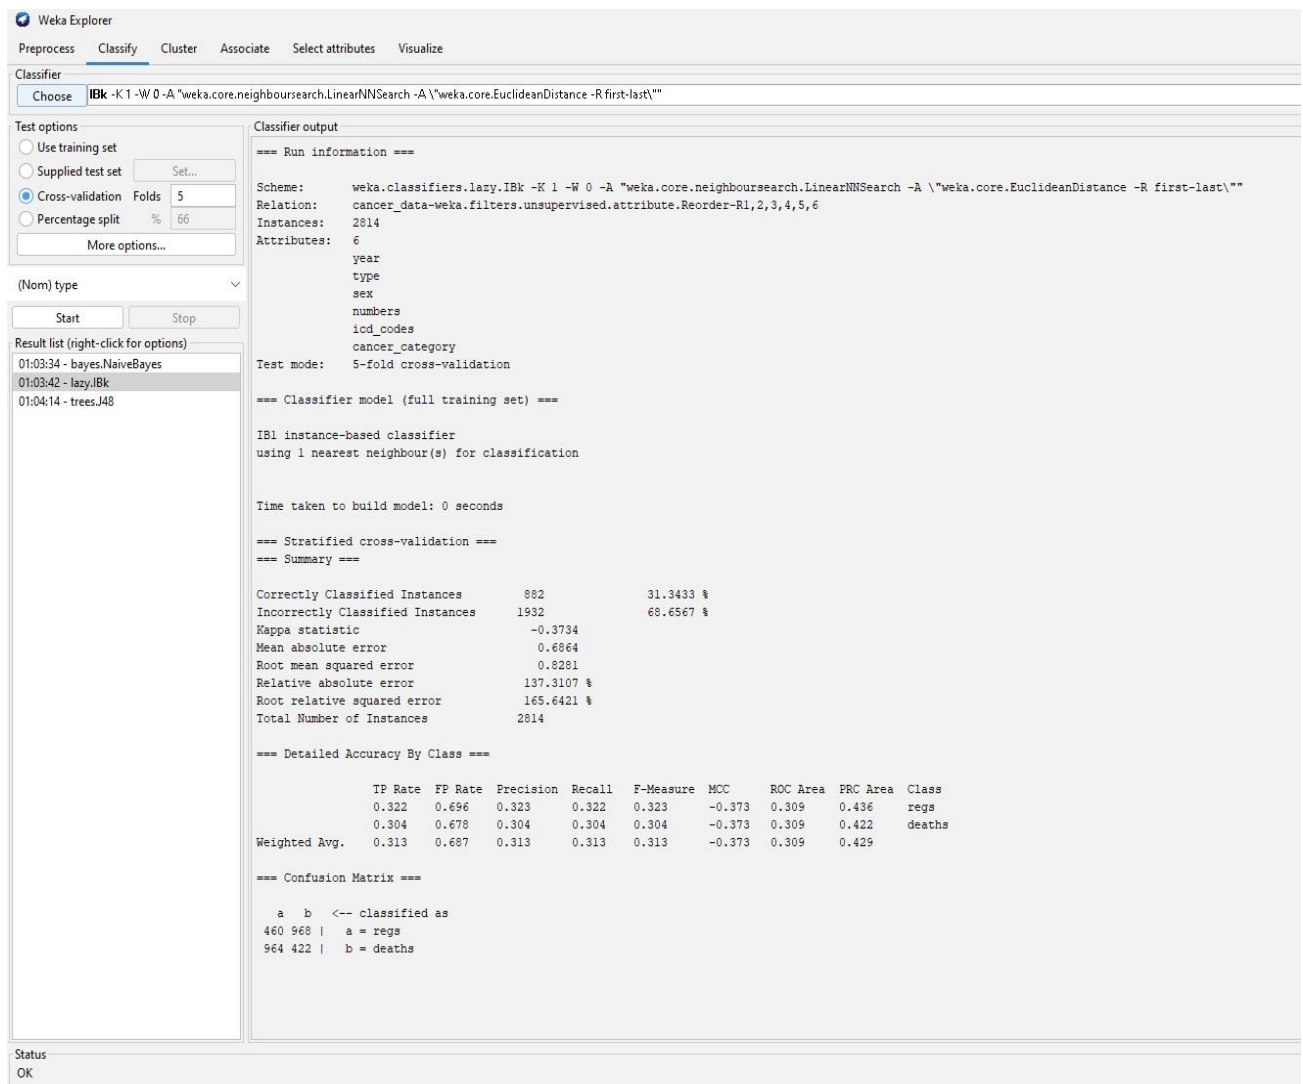

k-NN is a type of classification where the function is only approximated locally and all computation is deferred until function evaluation. Since this algorithm relies on distance for classification, if the features represent different physical units or come in vastly different scales then normalizing the training data can improve its accuracy dramatically.

A peculiarity of the k-NN algorithm is that it is sensitive to the local structure of the data.

#### Steps For development process of K –nearest neighbours :

First click on **classify** on the top menu bar then select **Choose** after that click on **lazy folder** then select **IBk**. it is **K –nearest neighbours**. Select and input **5 - Fold Cross Validation** .

After that select the **class** (top of the start button) here we have selected **(Nom) type** from our data set. Then click on **Start button**. The result will show.

*Figure 4 : K-NN Model developed using weka Tool*

### 3.4 : Decision Tree

A decision tree is a flowchart-like structure in which each internal node represents a "test" on an attribute (e.g. whether a coin flip comes up heads or tails), each branch represents the outcome of the test, and each leaf node represents a class label (decision taken after computing all attributes). The paths from root to leaf represent classification rules.

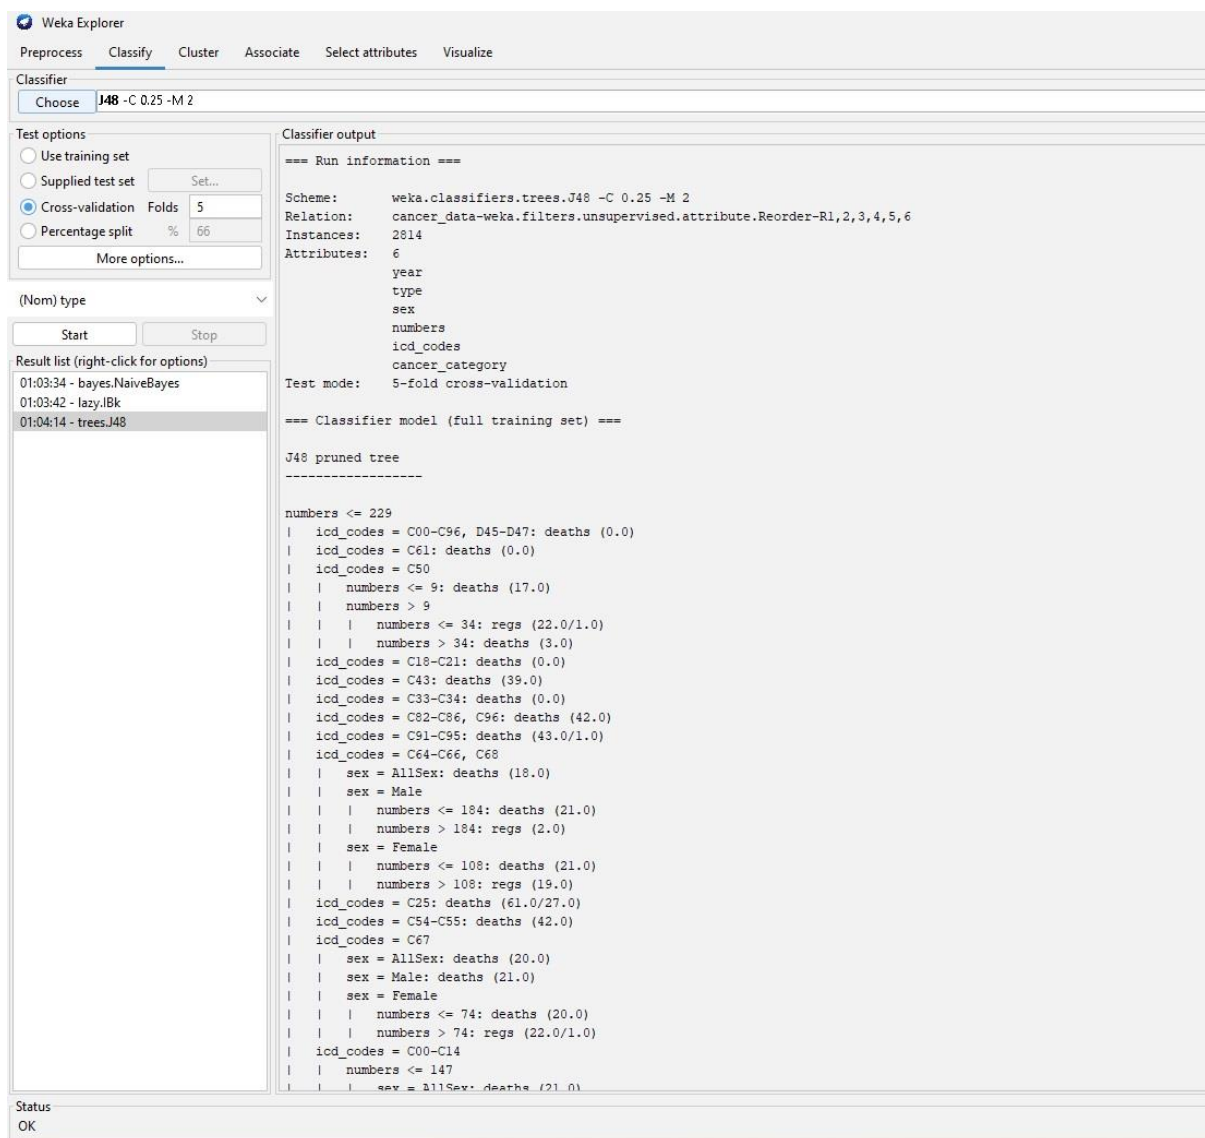

In decision analysis, a decision tree and the closely related influence diagram are used as a visual and analytical decision support tool, where the expected values (or expected utility) of competing alternatives are calculated.

A decision tree consists of three types of nodes: [1] Decision nodes – typically represented by squares

Chance nodes – typically represented by circles

End nodes – typically represented by triangles

Decision trees are commonly used in operations research and operations management. If, in practice, decisions have to be taken online with no recall under incomplete knowledge, a decision tree should be paralleled by a probability model as a best choice model or online selection model algorithm.

## Steps For development process of Decision Tree:

First click on **classify** on the top menu bar then select **Choose** after that click on **tree folder** then select **J48**. it is **Decision Tree**. Select and input **5 - Fold Cross Validation**.

After that select the **class** (top of the **start** button) here we have selected **(Nom) type** from our data set. Then click on **Start button**. The result will show.

Figure 5 : Decision Tree Model developed using weka Tool

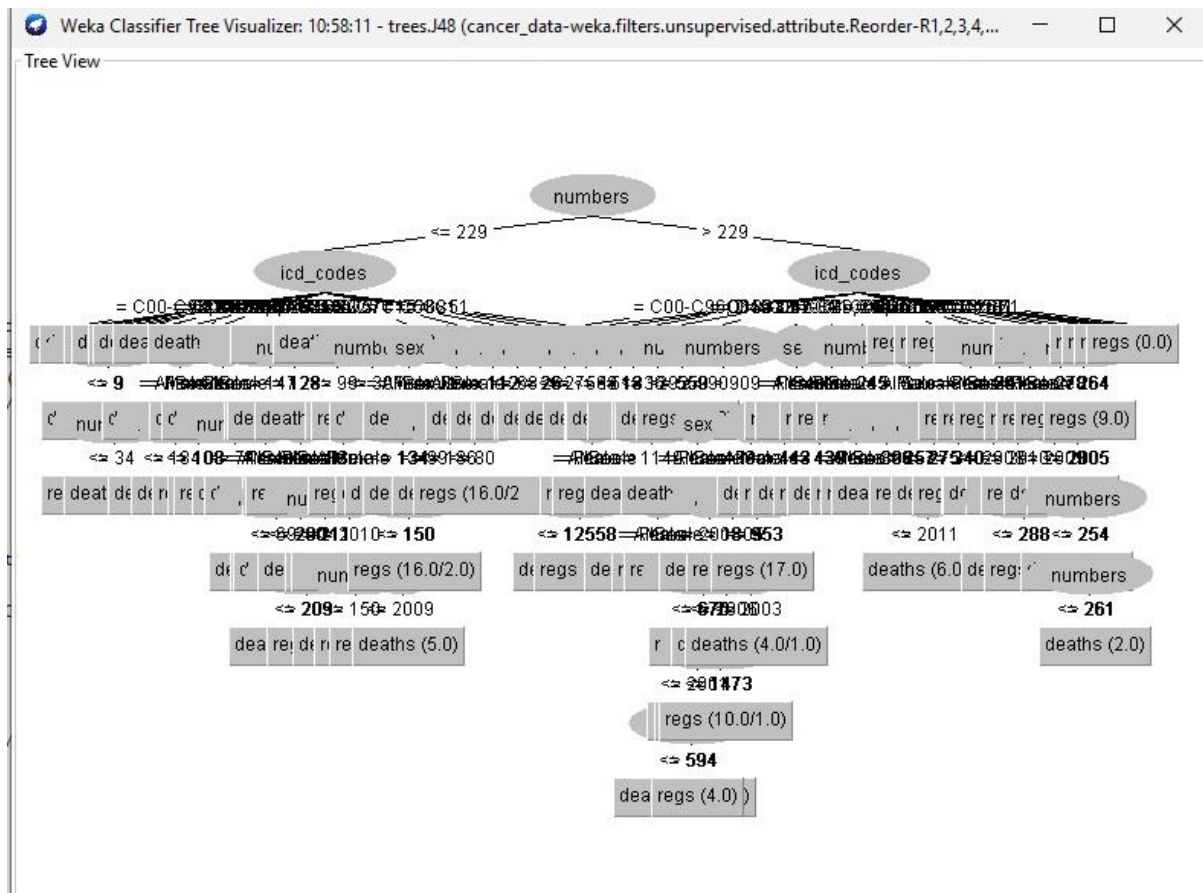

Figure 6: Decision Tree

For this Visual Tree ,Select the **trees J48** in the **Result List** then **Right Click** . After that Select **Visualize Tree** .

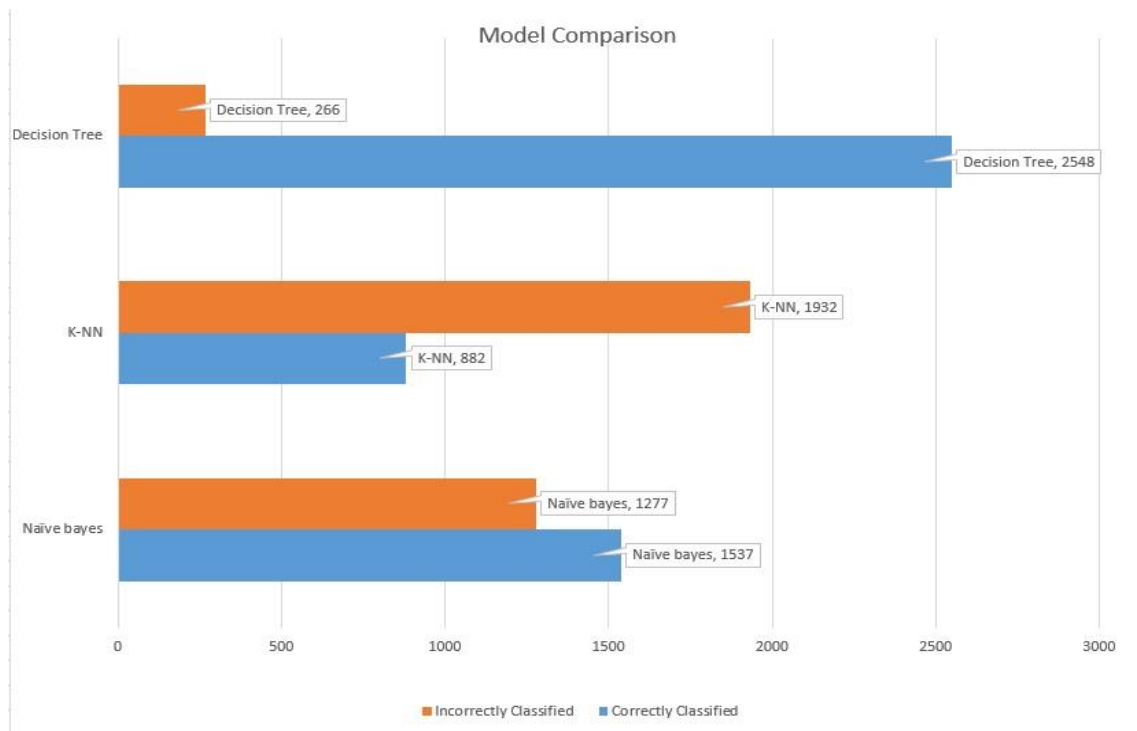

Figure 5 : The Bar chart we can see that Decision Tree is more efficient than other models , It can correctly classify 2548 from 2814 instances. Naïve Bayes can correctly classify 1537 from 2814 instances .K-NN can correctly classify 882 from 2814 instances

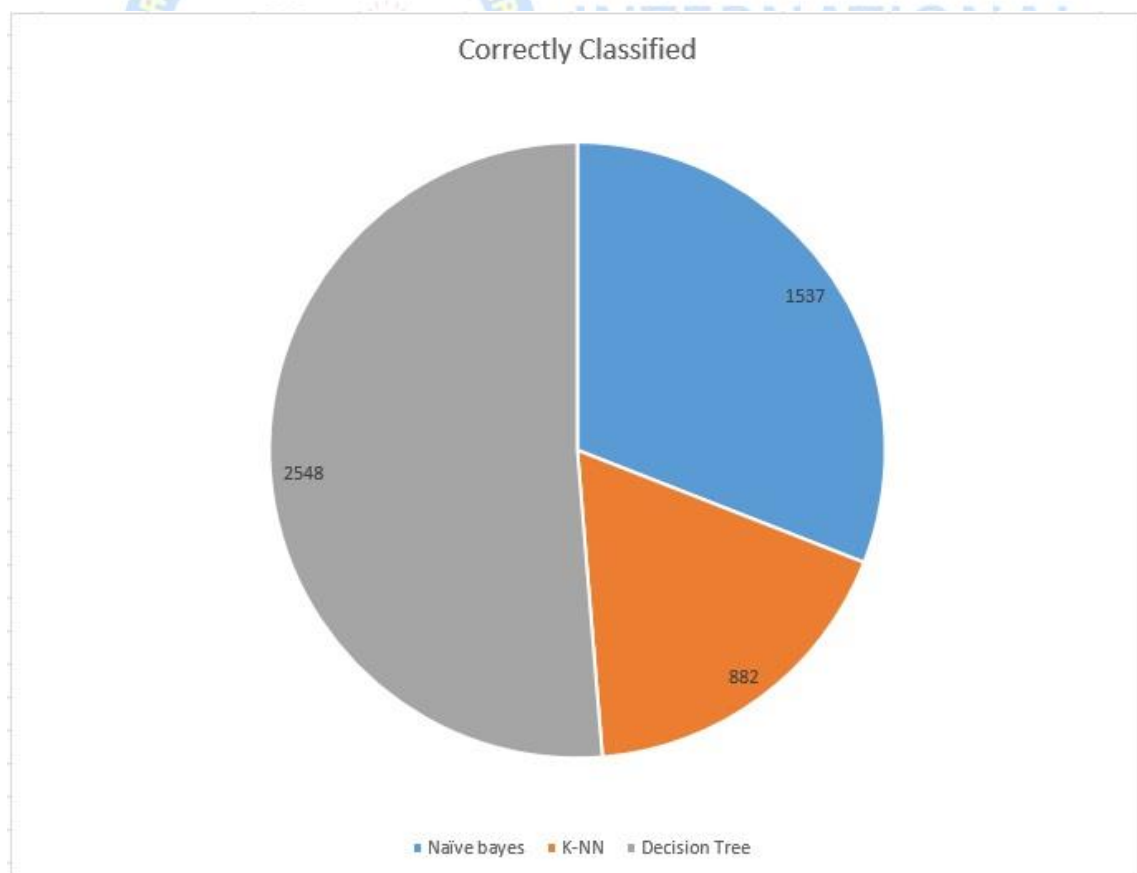

Figure 6: Pie chart showing the Amount of Correctly Classified Instances.

## Section 4: Discussion And Conclusion

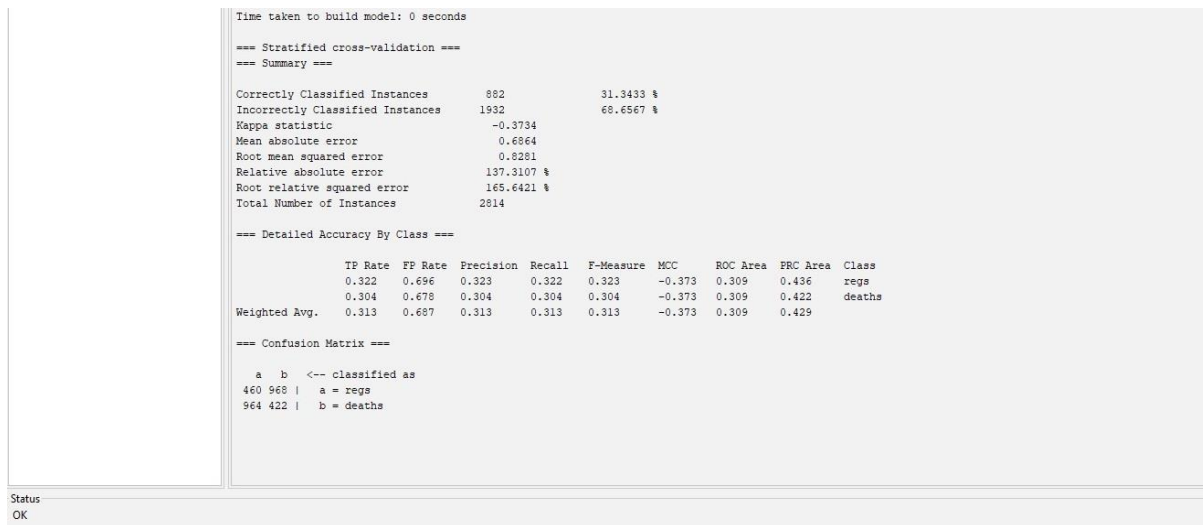

Figure 8: Confusion Matrix of K-NN

In this dataset(K-NN) there are only two classes, one is often regarded as “a=regs” and the other as “b=deaths”. This case the entries in the two rows and columns of the confusion matrix are referred to as regs and deaths. As there are only two classes in Cancer case dataset, the revised confusion matrix for cancer case test set according to regs and deaths true and false is given below

1. Of 1424 the instances classified as regs, 460 genuinely are regs (true regs) and the other 964 are really deaths (false deaths).
2. Of the 1390 instances classified as deaths, 968 are really regs (false deaths) and the other 422 are genuinely deaths (true deaths).

	a= regs	b=deaths
a= regs	460 (32.22%)	968(67.78%)
b=deaths	964 (69.56%)	422(30.44 %)

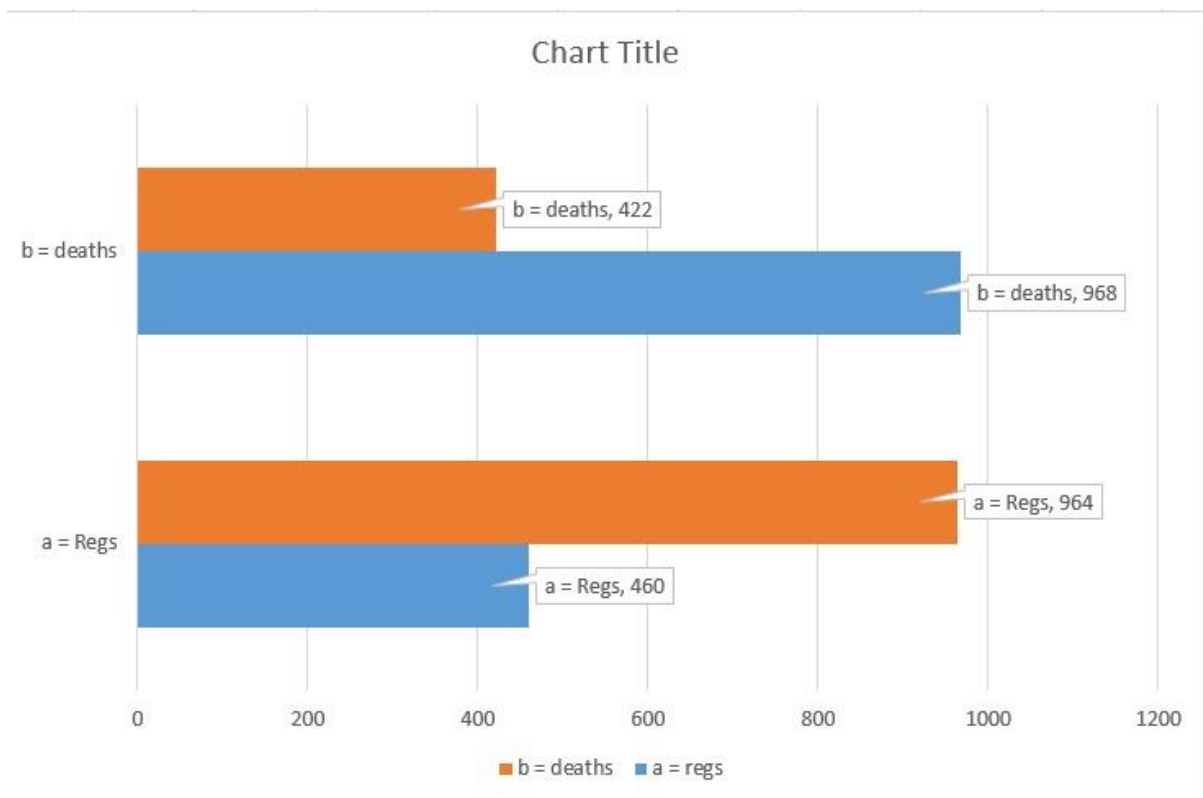

Figure: Chart of K-NN confusion matrix

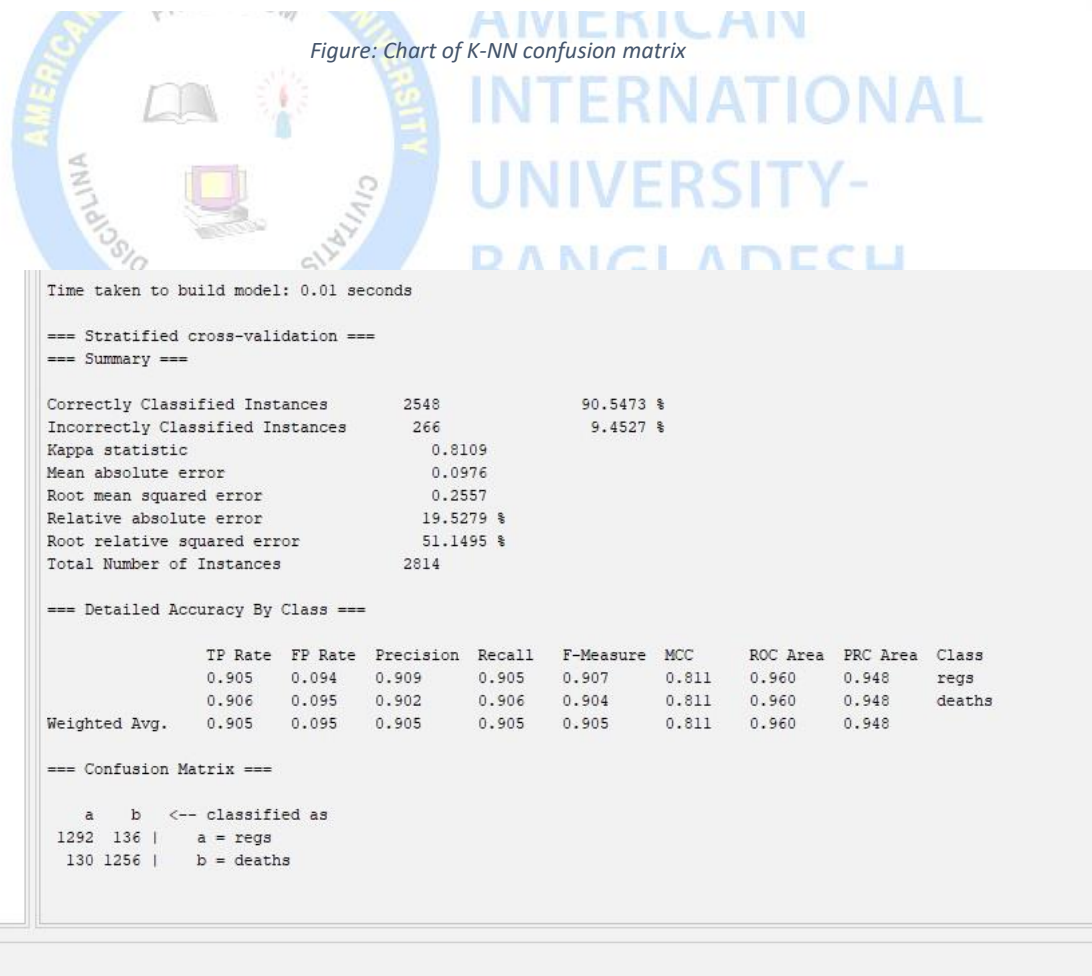

Figure 9: Confusion Matrix of Decision Tree

In this dataset (Decision Tree ) there are only two classes, one is often regarded as “a=regs” and the other as “b=deaths”. This case the entries in the two rows and columns of the confusion matrix are referred to as regs and deaths. As there are only two classes in Cancer case dataset, the revised confusion matrix for cancer case test set according to regs and deaths true and false is given below

1. Of 1422 the instances classified as regs, 1292 genuinely are regs (true regs) and the other 130 are really deaths (false deaths).
2. Of the 1392 instances classified as deaths, 136 are really regs (false deaths) and the other 1256 are genuinely deaths (true deaths).

	a= regs	b=deaths
a= regs	1292 (90.5 %)	136 (9.5%)
b=deaths	130 (9.4%)	1256 (90.6%)

Figure: Chart of Decision tree confusion matrix

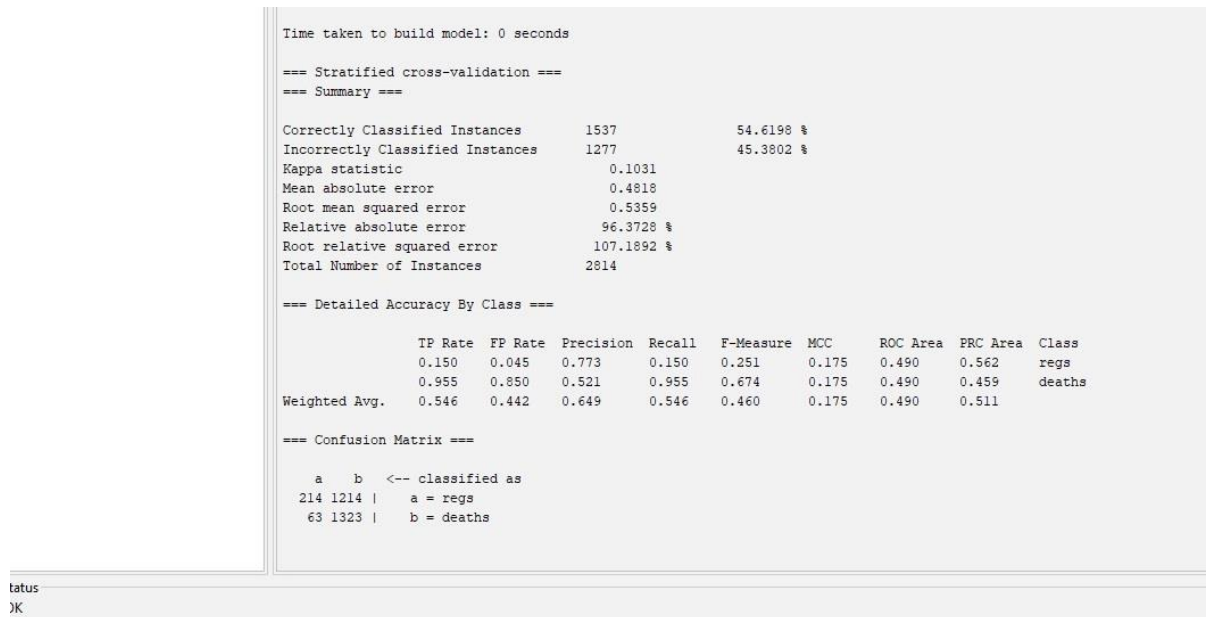

Figure 10 : Confusion Matrix of Naive bayes .

In this dataset (naïve Bayes) there are only two classes, one is often regarded as “a=regs” and the other as “b=deaths”. This case the entries in the two rows and columns of the confusion matrix are referred to as regs and deaths. As there are only two classes in Cancer case dataset, the revised confusion matrix for cancer case test set according to regs and deaths true and false is given below

1. Of 277 the instances classified as regs, 214 genuinely are regs (true regs) and the other 63 are really deaths (false deaths).
2. Of the 2537 instances classified as deaths, 1214 are really regs (false deaths) and the other 1323 are genuinely deaths (true deaths).

	a= regs	b=deaths
a= regs	217 (15.16%)	1214 ( 84.84%)
b=deaths	63 (4.5 %)	1323 (95.5 %)

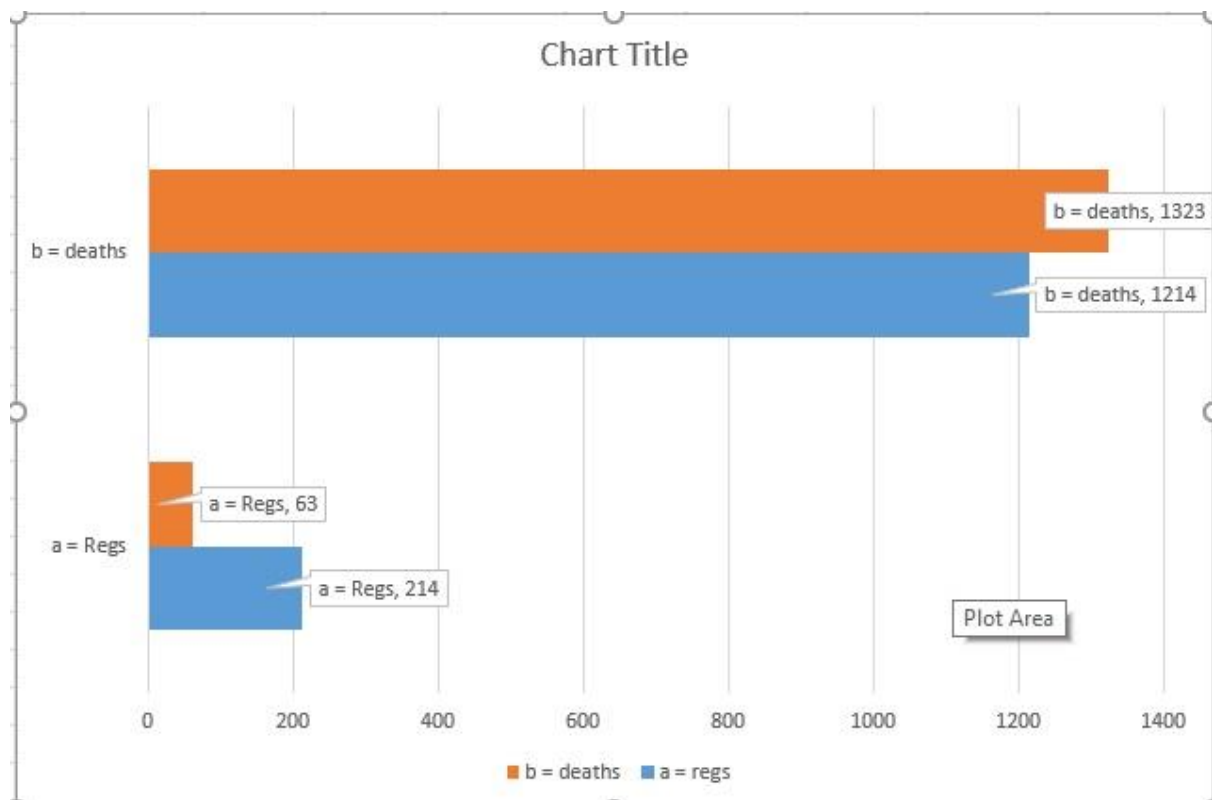

Figure: Chart of Naive Bayes confusion matrix

So for this specific Dataset Decision tree is Suitable. Because only Decision tree can correctly classify 2548 instance's from 2814 instances. Also from the confusion matrix we can see that in decision tree the false Regs and false deaths are minimum then other models. With a perfect classifier there would be no false Regs or false deaths. So we can say that Decision tree Model is suitable for this Data set. In this data set we have used 5-fold cross-validation for accuracy prediction.
